SUNMINT

Restoring the Amazon, one verified tree at a time

An introduction — prepared for Tony

SunMint finances small Amazonian farmers to restore degraded land through cacao agroforestry — and records every tree, every farm, and every family on a public, verifiable registry. This introduction lays out exactly what's built, what's proven, and what we're asking of a partner.

245	273.43	15	8
TREES INDIVIDUALLY VERIFIED	HECTARES UNDER RESTORATION	PARTNER FARMS	NATIVE SPECIES

16 October 2026

01 What's actually on the ground

Every tree SunMint counts is an individual, geolocated record — not an estimate. As of today, **245 trees are individually registered** across **22 plots** and **15 farms**, spanning **273.43 hectares** in the Amazon (Pará) and the Atlantic Forest (Bahia). Eight native species are represented, led by cacao hybrids (114 trees), Forastero (93), and Criolla (22), alongside Cumaru and four others.

The live SunMint impact map, showing registered plots against current satellite imagery of the pilot area near Altamira, Pará.

Every planting event has been documented on camera — **1,084 media items** (705 video, 379 photo) captured in the field and archived against each tree's record. And the program already moves real money to real people: on 15 October 2026, SunMint paid out for **86 verified trees** planted by students at a partner school in Pará — R$430, sent directly to each student by PIX.

> **A note on precision.** Planting, counting, and verifying are three different stages — and we don't collapse them. Trees are in the ground across all 22 plots; the partner cooperative is now working through the per-tree census for the balance. The 245 figure above is what's individually counted and on the record today, not a planting estimate.

What a restored forest grows into

Jedielcio Oliveira — who leads our cooperative partner, CEPOTX — beside one of the forest giants on the Transamazônica. This is the horizon SunMint plants toward: today's seedlings becoming tomorrow's canopy, on land that was degraded, not cleared from standing forest.

02 Who we work with, and how

SunMint works through existing rural institutions — never around them. Two kinds of partners make the program run.

Farmer cooperatives

Our Brazilian partner is **CEPOTX** — a central cooperative based in Altamira, Pará, led by Jedielcio Oliveira, coordinating four member cooperatives across the region. Fifteen farms are enrolled today, each one a real family enterprise with a named owner and a mapped plot.

The model is simple: **the farmer keeps the land and owns the trees.** SunMint provides upfront financing for costs the farmer can't carry alone — cacao takes about a year and a half to bear fruit — plus a route to long-term revenue through cacao and, eventually, carbon.

CFR Anapu students

Casa Familiar Rural de Anapu "Dorothy Stang" is a rural family school on the Transamazônica highway, teaching under a model where students alternate between classroom terms and time on their own family farms. Students plant native Amazonian trees on their family properties as part of the program.

Under a signed support agreement, each verified tree earns the student **R$5, paid directly by PIX** — native species only, with parental consent required for minors, and a public credential tied to every planted tree.

Why this scales: one classroom of students becomes dozens of new planting families, organically, well beyond what any single farm project could plant alone.

How we verify — three layers

> **1. Plant and verify at the tree**
> Every tree is its own record: GPS location, species, planting date, a photograph, and the identity of the person who planted it. Nothing is claimed that isn't evidenced.

> **2. Monitor it for life**
> Every six months, the planter submits two photos per tree — one with a standard card held against the trunk for scale, one of the full tree — so growth is measured for as long as the tree stands.

> **3. Record it permanently**
> Every action is written to a public registry and shown on the live impact map — exactly the kind of monitoring trail a carbon registry will later require.

The discipline underneath all of it: we plant on **already-degraded land** — pasture, cleared ground — never standing forest. It's the only baseline with a defensible claim, and we'd rather under-claim than over-claim.

03 Where things stand, plainly

We'd rather a partner hear this from us directly than discover it later: **no registry-issued carbon credits exist yet.** SunMint has built and verified a real physical asset on the ground. It hasn't yet converted that asset into a tradeable credit — and those are two genuinely different things.

Two lanes, and a tree only sits in one

Contribution lane — live today. "This support funded this tree." Runs entirely on our tree-level traceability, needs no registry, and is already visible on the public impact map.

Credit lane — not yet started. A tradeable carbon credit requires a chosen methodology, a monitoring design built around it, independent validation, formal registration, and issuance. None of that has begun.

"Listing" can mean three different things, and it's worth being specific about which one is on the table: a project listing with a registry, credits listed on an exchange (only possible after issuance), or a company going public — unrelated to either.

The two things that gate any credit path

Carbon-rights assignment	A signed agreement with each cooperative establishing who owns the carbon from each tree, with an explicit benefit split. This is the first document any serious buyer or auditor will ask for.
Registry & methodology	Which standard to build toward — leading candidate is Verra's VM0047 agroforestry methodology, with Isometric Agroforestry and Gold Standard also on the table. This choice shapes the monitoring design from the very first tree.

A sense of scale — modeled, not promised

Using a published agroforestry benchmark (roughly 3.85 tonnes of CO_2 per hectare per year), a program at 10,000 hectares would generate on the order of 38,500 tonnes annually — somewhere between **US$1.1M and US$2.9M a year** depending on the credit market accessed. The actual rate for cacao-based agroforestry specifically won't be known until a chosen methodology's growth model is run against our own plots. This is a yardstick for the conversation, not a forecast.

04 A few numbers worth getting straight

A few figures tend to circulate informally around SunMint. For the record:

"3,000–3,500 trees planted"
That figure comes from a trees-funded counter (how many tree-plantings have been sponsored), not from individual on-the-ground verification. 245 are individually counted and on the record today; more are planted and awaiting their turn in the census. Funded and verified are not the same claim.

"100 hectares of standing forest"
A separate conversation about an existing virgin-forest property came up recently. Standing forest doesn't carry an additionality case under our restoration model — the land has to have been non-forest, not pristine forest being protected. It's simply a different kind of project than what SunMint does.

"A 25,000-hectare government programme"
We haven't been able to verify this figure against our own records. The confirmed total under SunMint today is 273.43 hectares.

05 What we'd ask of a listing partner

1. **What claim is the eventual buyer making?** A contribution or insetting claim can run on our tree-level traceability today. A compensation claim needs rated registry credits — a different standard entirely, and it's worth knowing which one we're building toward.
2. **Which kind of "listing" is actually on offer** — a registry project, an exchange listing, or something else?
3. **We'd want a partner at the table for the carbon-rights assignment** with each cooperative — the structural document everything else builds on.

06 See it for yourself

Numbers only go so far. These are unedited clips from the field — a school and a farm, back to back — for anyone who wants to go past the spreadsheet to the ground truth it's built on.

THE STUDENTS — CASA FAMILIAR RURAL DE ANAPU

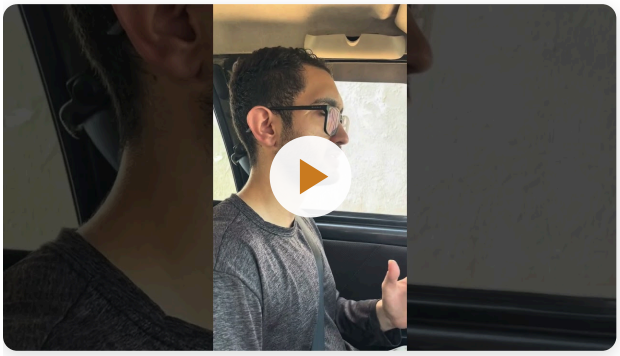

Why the R$5-per-tree support matters — keeping students connected to their family land. **youtu.be/byTlnA12QlQ**
